

Premier League 2024/25 Performance Analysis Journal

Project purpose

I am investigating which performance factors were most strongly associated with Premier League points in 2024/25. I also want to identify teams whose actual results were better or worse than their underlying match statistics suggested.

Intended audience

Football supporters, analysts and decision-makers who want a clear, data-driven overview of team performance during the 2024/25 Premier League season.

Meaning of success

In the analysis, team success is measured primarily by total Premier League points. For me personally, project success will be measured by how confidently I can use Power BI and apply what I learned to my next independent project.

Meaning of overperformance or underperformance

Overperformance means a team earned more points than expected based on its shots-on-target difference, while underperformance means it earned fewer points than expected.

Personal learning objective

My goal is to become comfortable enough with Power BI that I can approach my next project more independently.

Data preparation

The original dataset contained one row per match, with home and away statistics stored in separate columns. I transformed it into a team-match table containing one row per team per match. This produced 760 rows and made it possible to

calculate team totals consistently across home and away fixtures.
I validated the transformation by confirming that every team played 38 matches and that the calculated points matched the final Premier League table.

Initial findings

- Liverpool earned the most home points (46) and away points (38), suggesting that their league dominance was consistent across both venues rather than dependent primarily on their home performance.
- Brentford recorded the league's highest shot accuracy (41.72%) and shot-conversion rate (14.97%), indicating that they were highly efficient at directing attempts on target and turning shots into goals.
- Liverpool and Arsenal showed the strongest attacking-defensive balance. Liverpool paired the league's highest scoring output (86 goals) with a strong defensive record, while Arsenal conceded the fewest goals (34) and still scored 69. Liverpool's more productive attack helped them finish ten points ahead.
- Total shot volume had a strong positive correlation with points ($r = 0.83$), indicating that higher-volume shooting teams generally earned more points.

Relationship Between Performance Factors and Points

Performance factor	Correlation with total points
Goals conceded	-0.91
Goals scored	0.89
Total shots	0.83
Shot conversion rate	0.63

Goals conceded had the strongest relationship with total points. The negative value means that teams generally earned fewer points as they conceded more goals.

Goals scored and total shots also had strong positive relationships with points. Shot conversion showed a positive relationship, although it was weaker than the other factors.

These results show association rather than causation and are based on the 20 Premier League teams in the 2024/25 season.

Executive overview completed: I created a league table, league-level KPI cards, a match-outcome breakdown, and attacking and defensive rankings. I also disabled the league table's interaction with the KPI cards so they continue showing full-season league totals when a team is selected.

Nottingham Forest earned around 15 more points than our shot-based model expected, suggesting that they overperformed their underlying shots-on-target statistics.

Man United earned around 16 fewer points than the shot-based model expected, suggesting that they underperformed relative to their shots-on-target difference.

This model uses shots-on-target difference as a simple performance proxy. It does not account for chance quality, shot location, goalkeeper performance or other match circumstances, so the results should not be treated as official xPoints.

Why I chose this project

I chose this project because I love football and regularly follow the Premier League, so I was genuinely interested in analysing the data. I also wanted to learn how to build analytical models in Power BI because I often see football data analysts online, and I am interested in exploring that field myself.

Final findings

- Goals conceded had the strongest relationship with league points, with a correlation of -0.91. Teams that conceded fewer goals generally earned more points.
- Goals scored also had a strong relationship with points at 0.89, followed by total shots at 0.83.
- Liverpool finished first with 84 points and led the league in both home and away points.
- Brentford recorded the highest shot conversion rate at 14.97%.
- Nottingham Forest exceeded the shot-based expectation by 15.36 points, while Manchester United finished 16.32 points below expectation.
